

# Date Events

---

A faceless scriptable application which adds the missing choose date API

Like System Events there is no UI in Date Events (except the temporary date panel). It quits automatically after 5 minutes of inactivity.

To choose a date is pretty simple

```
set theDate to choose date
```

which shows a graphical interface with date and time.

You can set the style to `textual` and `textual with stepper` and there are a few options for the date and time appearance.

Additionally there are some APIs to convert date to string and vice versa for custom string format/template and locale, and also some calendar APIs to get the start of the day or to check if a date is in yesterday, today or tomorrow.

You can add multiple calendars for example the iso8601 calendar and other international calendar types.

See the sample script for the available APIs.

## System Requirements:

macOS 10.15 Intel or Apple Silicon  
The app is sandboxed and notarized.
